Linear algebra revisited

"Simplest" equation in mathematics:
$y = Ax$ for (known) $m \times N$ matrix A and $y \in \mathbb{R}^m$
Task: recover $x \in \mathbb{R}^N$ from y

Studied from many points of view:
Linear algebra: existence, uniqueness
Numerical analysis: stability, speed
Special methods for structured matrices A

"New" point of view:
          . . . we look for a solution x with special structure!

The setting of compressed sensing
Backgrounds of compressed sensing

"Large" applications

Linear algebra revisited
Sparsity enters the picture
Randomness enters the picture
Motivating example
Sparse recovery

The world is compressible!

Natural images can be sparsely represented by wavelets!...JPEG2000

...today, we measure all the data (megapixels, i.e. millions), to throw the most of them away!

The setting of compressed sensing
Backgrounds of compressed sensing
Extensions, tricks, "small" applications
"Large" applications

Linear algebra revisited
Sparsity enters the picture
Randomness enters the picture
Motivating example
Sparse recovery

Sparse solutions

Simplified situation:

> Let A be an $m \times N$ matrix, and let $x \in \mathbb{R}^N$ be sparse,
> i.e. with $\|x\|_0 := \#\{i : x_i \neq 0\}$ small.
> Recover x from $y = Ax$.

Natural assumption:

Given $x \in \mathbb{R}^N$. By experience, we "know" (i.e. expect) that there exists an orthonormal basis Φ with $x = \Phi c$ such that c is sparse

Task:

> Let A be an $m \times N$ matrix, let $x = \Phi c \in \mathbb{R}^N$ with Φ an ONB
> and $\|c\|_0$ small. Recover x from $y = A\Phi c$.

The setting of compressed sensing

Extensions, tricks, "small" applications
"Large" applications

Linear algebra revisited
Sparsity enters the picture
Randomness enters the picture
Motivating example
Sparse recovery

Prony's method (1795)

Let x be s-sparse, i.e. $\|x\|_0 \leq s$

Then x can be recovered by asking $2s$ (non-linear) queries:
- locations of non-zero positions
- and their value
$\implies$ $2s$ degrees of freedom.

Theorem (Prony, 1795):
Let $N \geq 2s$. Then every s-sparse vector $x \in \mathbb{R}^N$ can be recovered (by a "practical" procedure) from its first $2s$ discrete Fourier coefficients.

- not stable with respect to "defects" of sparsity, i.e. fails for "nearly sparse" vectors
- not robust with respect to noise of the measurements

The setting of compressed sensing
Backgrounds of compressed sensing
Extensions, tricks, "small" applications
"Large" applications

Linear algebra revisited
Sparsity enters the picture
Randomness enters the picture
Motivating example
Sparse recovery

Let's play: $\|x\|_0 = 1$, i.e. $x = \lambda e_j$

$$A := \begin{pmatrix} 1 & 0 & \ldots & 0 & 0 & \ldots & 0 \\ 0 & 1 & \ldots & 0 & 0 & \ldots & 0 \\ \vdots & & \ddots & \vdots & \vdots & \ldots & \vdots \\ 0 & 0 & \ldots & 1 & 0 & \ldots & 0 \end{pmatrix} \in \mathbb{R}^{m \times N} \quad \text{is just bad...}$$

$$A := \begin{pmatrix} 1 & 1 & \ldots & 1 \\ 1 & 2 & \ldots & N \end{pmatrix}; A(\lambda e_j) = \begin{pmatrix} \lambda \\ j\lambda \end{pmatrix}.$$

But

$$A\Big(\frac{N-2}{N-1}, 0, \ldots, 0, \frac{1}{N-1}\Big)^T = Ae_2 = \begin{pmatrix} 1 \\ 2 \end{pmatrix} \implies \text{bad stability}$$

The setting of compressed sensing

"Large" applications

Linear algebra revisited
Sparsity enters the picture
Randomness enters the picture
Motivating example
Sparse recovery

Random matrices

Let $A = (a_{k,l})$, then $A(\lambda e_j) = \lambda a_{\cdot j}$ is co-linear with $a_{\cdot j}$, the jth column of A
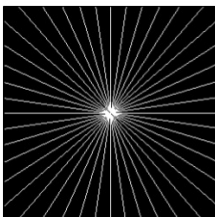

If the columns of A are normalized, "nearly orthogonal", we can easily find j - in a stable way.
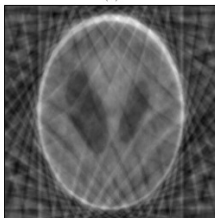

Concentration of measure phenomenon:
If $a_{k,l}$ are i.i.d. random variables (Gaussian, Bernoulli, ...), then this is the case already for surprisingly small m's... $m \approx \log N$.

Sparse recovery

Natural minimization problem:

Given an $m \times N$ matrix A and $y \in \mathbb{R}^m$, solve

$$\min_x \|x\|_0 \ \text{ subject to } \ y = Ax$$

This minimization problem is NP-hard!

$p \leq 1$ - promotes sparsity

$p \geq 1$ - convex problem

Basis pursuit (ℓ_1-minimization; Chen, Donoho, Saunders - 1998):

$$\min_x \|x\|_1 \ \text{ subject to } \ y = Ax$$

$\longrightarrow$ This can be solved by linear programming!

Summary of the introduction

Situation:

Given an $m \times N$ matrix A and a sparse $x \in \mathbb{R}^N$,
recover x from $y = Ax$!

'Initial' papers:

- ▶ E. Candès, J. Romberg, T. Tao, *Stable signal recovery from incomplete and inaccurate measurements*, Comm. Pure Appl. Math. **59** (2006), 1207–1223.

- ▶ D. Donoho, *Compressed sensing*, IEEE Trans. Inform. Theory **52** (2006), 1289–1306.

Basic message:

Sparse high-dimensional signals can be recovered efficiently
from a small set of linear, non-adaptive measurements!
. . . random measurements, ℓ_1-minimization

Directions

Situation:

> *Given an $m \times N$ matrix A and an s-sparse $x \in \mathbb{R}^N$,*
> *recover x from $y = Ax$!*

Fundamental (theoretical) questions:

- What is the minimal number $m = m(s, N)$ of measurements?
- For which sensing matrices is the task (uniquely) solvable?
- "Good" algorithms for recovery of x?
- Stability - i.e. "nearly sparse" x's?
- Robustness - i.e. noisy measurements?

The setting of compressed sensing
Backgrounds of compressed sensing
Extensions, tricks, "small" applications
"Large" applications

Sparse Recovery Conditions
Sensing Matrices
Algorithms
Stability, robustness

Notation

Sparsity: $x \in \mathbb{R}^N$ is s-sparse, if

$$\|x\|_0 \leq s.$$

We often write: $\Sigma_s = \{x \in \mathbb{R}^N : x \text{ is } s\text{-sparse}\}$.

Compressibility: $x \in \mathbb{R}^N$ is compressible, if it can be well approximated by sparse vectors, i.e. when its best s-term approximation

$$\sigma_s(x)_p := \min_{\tilde{x} \in \Sigma_s} \|x - \tilde{x}\|_p$$

is small.

The setting of compressed sensing
Backgrounds of compressed sensing
Extensions, tricks, "small" applications
"Large" applications

Sparse Recovery Conditions
Sensing Matrices
Algorithms
Stability, robustness

Null Space Property

Definition:
$A \in \mathbb{R}^{m \times N}$ has the Null Space Property (NSP) of order s if

$$\|1_\Lambda h\|_1 < \tfrac{1}{2}\|h\|_1 \quad \text{for all } h \in \ker(A) \setminus \{0\} \text{ and for all } \#\Lambda \le s.$$

Theorem (*Cohen, Dahmen, DeVore - 2008*):
Let $A \in \mathbb{R}^{m \times N}$ and $s \in \mathbb{N}$. TFAE:

(i) For every $y \in \mathbb{R}^m$, there exists at most one solution in Σ_s of

$$\min_x \|x\|_1 \text{ subject to } y = Ax.$$

(ii) A satisfies the null space property of order s.

Sparse Recovery Conditions
Sensing Matrices
Algorithms
Stability, robustness

Restricted Isometry Property

Definition:
$A \in \mathbb{R}^{m \times N}$ has the Restricted Isometry Property (RIP) of order s
with RIP-constant $\delta_s \in (0, 1)$ if

$$(1 - \delta_s)\|x\|_2^2 \leq \|Ax\|_2^2 \leq (1 + \delta_s)\|x\|_2^2 \qquad \forall x \in \Sigma_s.$$

Theorem (*Cohen, Dahmen, DeVore - 2008; Candès - 2008*):
Let $A \in \mathbb{R}^{m \times N}$ with RIP of order $2s$ with $\delta_{2s} < 1/3$. Then A has
NSP of order s.

The setting of compressed sensing

Extensions, tricks, "small" applications
"Large" applications

Sparse Recovery Conditions
Sensing Matrices
Algorithms
Stability, robustness

Sensing matrices

Random matrices (*Candès, Donoho, et al.; 2006–2011*)
Let A be an $m \times N$-matrix with independent subgaussian entries. If

$$m \geq C\delta^{-2}s\log(N/s),$$

then A satisfies the RIP of order s with $\delta_s \leq \delta$ with prob. at least

$$1 - 2\exp(-c\delta^2 m) \quad \text{'overwhelmingly high probability'}.$$

Optimality (through high-dimensional geometry):
Stable recovery of s-sparse vectors is possible only for
$m \geq Cs\log(N/s)$.

Stability, robustness

Stability, robustness

The theory can be easily generalized to include

- *stability* (x not sparse but compressible) and
- *robustness* (measurements with noise)

Let $y = Ax + e$, $\|e\|_2 \leq \eta$, where A has the *Robust Null Space Property* of order s. Then

$$x^{\#} := \arg\min_{x} \|x\|_1 \text{ subject to } \|Ax - y\|_2 \leq \eta$$

satisfies

$$\|x - x^{\#}\|_1 \leq C\sigma_s(x)_1 + D\sqrt{s}\,\eta$$

and

$$\|x - x^{\#}\|_2 \leq \frac{C}{\sqrt{s}}\sigma_s(x)_1 + D\eta.$$

"Matrix completion", or low-rank matrix recovery

The theory applies to other sorts of sparsity!
x sparse means, that some (unknown) of its possible degrees of freedom are not used (i.e. equal to zero)

The same is true for low-rank matrices!

"Large" applications

Matrix completion
Phase retrieval
Data separation
ℓ_1-SVM

Low-rank matrix recovery

Let $X \in \mathbb{C}^{n_1 \times n_2}$ be a matrix of rank at most r.
Let $y = \mathcal{A}(X) \in \mathbb{C}^m$ be the (linear) measurements of X.

We "want" to solve

$$\underset{Z \in \mathbb{C}^{n_1 \times n_2}}{\arg \min} \ \mathrm{rank}(Z) \quad s.t. \ \mathcal{A}(Z) = y.$$

$\mathrm{rank}(Z) = \|(\sigma_1(Z), \sigma_2(Z), \dots)\|_0$ gets replaced by
the nuclear norm $\|Z\|_* = \|(\sigma_1(Z), \sigma_2(Z), \dots)\|_1 = \sum_i |\sigma_i(Z)|$.

The convex relaxation is then

$$\underset{Z \in \mathbb{C}^{n_1 \times n_2}}{\arg \min} \ \|Z\|_* \quad s.t. \ \mathcal{A}(Z) = y.$$

The setting of compressed sensing
Backgrounds of compressed sensing
Extensions, tricks, "small" applications
"Large" applications

Matrix completion
Phase retrieval
Data separation
ℓ_1-SVM

Matrix completion

If $\mathcal{A}(X)$ are selected entries of $X \implies$ *Matrix Completion*
Few entries are known, the remaining are to be filled up!

Typical task for *recommendation systems*: Amazon, Netflix, . . .
Certain users ranked some of the products, we would like to predict
if other users would like different products. . .

Certainly impossible if:
$X = e_i \otimes e_j$ or
$X = e_1 \otimes v$

For both the theory and the practice: eigenvectors of X incoherent
with e_j, $j = 1, \ldots, m$. Then stable and robust recovery of an $N \times N$
matrix X of rank r needs only $\mathcal{O}(r\, N \log^2 N)$ measurements.

The setting of compressed sensing
Backgrounds of compressed sensing
Extensions, tricks, "small" applications
"Large" applications

Matrix completion
Phase retrieval
Data separation
ℓ_1-SVM

Phase retrieval

Setting:
Reconstruct the signal x from the magnitude of its discrete Fourier transform $\hat{x}$

General setting:
x given, $b_k = |\langle a_k, x \rangle|^2$, $k = 1, \ldots, m$ known, recover x!

Frequent problem (i.e. astronomy, crystallography, optics), different algorithms exist...

PhaseLift:
quadratic measurements of x are "lifted up" and become linear measurements of the matrix $X := xx^*$:

$$|\langle a_k, x \rangle|^2 = \text{Tr}(x^* a_k a_k^* x) = \text{Tr}(a_k a_k^* x x^*) = \text{Tr}(A_k X) = \langle A_k, X \rangle_F,$$

where $A_k := a_k a_k^*$

ℓ_1-SVM

For $\{x_1, \ldots, x_m\} \subset \mathbb{R}^N$ and $\{y_1, \ldots, y_m\} \subset \{-1, 1\}$,
the *Support Vector Machine* wants to separate the sets

$$\{x_i : y_i = -1\} \quad \text{and} \quad \{x_i : y_i = +1\}$$

by a linear hyperplane, i.e. finds $w \in \mathbb{R}^N$ and $b \in \mathbb{R}$ with

$\langle w, x_i \rangle - b > 0 \qquad \text{for} \quad y_i = 1,$
$\langle w, x_i \rangle - b < 0 \qquad \text{for} \quad y_i = -1.$

It maximizes the size of the margin around the separating hyperplane.

The setting of compressed sensing
Backgrounds of compressed sensing
Extensions, tricks, "small" applications

## Magnetic Resonance Imaging

MRI exhibits several important features, which suggest using CS:

1. MRI images are naturally sparse (in an appropriate transform and domain).

2. MRI scanners acquire encoded samples, rather then direct pixel samples.

3. Sensing is "expensive" (damage to patient, costs).

4. Processing time does not play much role.

MRI applies additional magnetic fields on top of a strong static magnetic field. The signal measured $s(t)$ is the Fourier transform of the object sampled at certain frequency $\bar{k}(t)$.
